## Normalization in the relational model.

An anomaly is an inconsistent, incomplete, or contradictory state of the database

- Insertion anomaly - user is unable to insert a new record when it should be possible to do so
- Deletion anomaly - when a record is deleted, other information that is tied to it is also deleted
- Update anomaly -a record is updated, but other appearances of the same items are not updated
The purpose of the normalization in a database environment is:
- to develop a good description of the data, its relationships and constraints
- to produce a stable set of tables(relations) that
- is a faithful model of the enterprise
- is highly flexible
- reduces redundancy-saves space and reduces inconsistency in data.
- is free of update, insertion and deletion anomalies

## Example 1

| CourseNo | studID | studLastName | fID | schedule | room | grade |
| :--- | :--- | :--- | :--- | :--- | :--- | :--- |
| ART103A | S1001 | Smith | F101 | MWF9 | H221 | A |
| ART103A | S1010 | Burns | F101 | MWF9 | H221 |  |
| ART103A | S1006 | Lee | F101 | MWF9 | H221 | B |
| CSC201A | S1003 | Jones | F105 | TUTHF10 | M110 | A |
| CSC201A | S1006 | Lee | F105 | TUTHF10 | M110 | C |
| HST205A | S1001 | Smith | F202 | MWF11 | H221 |  |

- Update anomaly: If schedule of ART103A is updated in first record, and not in second and third - inconsistent data
- Deletion anomaly: If record of student S1001 is deleted, information about HST205A class is lost also
- Insertion anomaly: It is not possible to add a new class, for MATH101A , even if its teacher, schedule, and room are known, unless there is a student registered for it, because the key contains studID

A table (relation) is in an UNF (undefined normal form) if it contains two or more data in a cell.

| studID | studLastName | major | credits | status | socSecNbr |
| :--- | :--- | :--- | :--- | :--- | :--- |
| S1001 | Smith | History | 90 | Senior | 100222500 |
| S1003 | Jones | Math | 95 | Senior | 222333444 |
| S1006 | Lee | CSC <br> Math | 15 | Freshman | 088111222 |
| S1010 | Burns | Art | 63 | Junior | 099111222 |
| S1060 | Jones | CSC | 25 | Freshman | 064624123 |

116
Mariana Kant - Relational model Normalization

The "major" attribute is not single-valued for each tuple.
1NF First Normal Form

1. A relation is in 1 NF if every attribute is single-valued for each tuple
2. Each cell of the table has only one value in it
3. Domains of attributes are atomic: no sets, lists, repeating fields or groups allowed in domains

## UNF to 1 NF

## Solve the repeats

1. For each multi-valued attribute, create a new table, in which you place the key of the original table and the multi-valued attribute. Keep the original table, with its key.

| studID | studLastName | credits | status | socSecNbr |
| :--- | :--- | :--- | :--- | :--- |
| S1001 | Smith | 90 | Senior | 100222500 |
| S1003 | Jones | 95 | Senior | 222333444 |
| S1006 | Lee | 15 | Freshman | 088111222 |
| S1010 | Burns | 63 | Junior | 099111222 |
| S1060 | Jones | 25 | Freshman | 064624123 |

| studID | major |
| :--- | :--- |
| S1001 | History |
| S1003 | Math |
| S1006 | Math |
| S1006 | CSC |
| S1010 | Art |
| S1060 | CSC |

2. If the number of repeats is limited, make additional columns for multiple values

| studID | studLastName | major1 | major2 | credits | status | socSecNbr |
| :--- | :--- | :--- | :--- | :--- | :--- | :--- |
| S1001 | Smith | History |  | 90 | Senior | 100222500 |
| S1003 | Jones | Math |  | 95 | Senior | 222333444 |
| S1006 | Lee | CSC | Math | 15 | Freshman | 088111222 |
| S1010 | Burns | Art |  | 63 | Junior | 099111222 |
| S1060 | Jones | CSC |  | 25 | Freshman | 064624123 |

3. "Flatten" the original table by making the multi-valued attribute part of the key

| studID | studLastName | major | credits | status | socSecNbr |
| :--- | :--- | :--- | :--- | :--- | :--- |
| S1001 | Smith | History | 90 | Senior | 100222500 |
| S1003 | Jones | Math | 95 | Senior | 222333444 |
| S1006 | Lee | CSC | 15 | Freshman | 088111222 |
| S1006 | Lee | Math | 15 | Freshman | 088111222 |
| S1010 | Burns | Art | 63 | Junior | 099111222 |
| S1060 | Jones | CSC | 25 | Freshman | 064624123 |

## 2NF Second Normal Form

The 2NF is based on the concept of functional dependency.
A functional dependency (FD) is a type of relationship between attributes
If $\boldsymbol{\alpha}$ and $\boldsymbol{\beta}$ are sets of attributes of relation $R$, we say that $\boldsymbol{\beta}$ is functionally dependent on $\boldsymbol{\alpha}$ if each $\boldsymbol{\alpha}$ value in $R$ has associated with it exactly one value of $\boldsymbol{\beta}$ in $R$.
Alternatively, if two tuples have the same $\boldsymbol{\alpha}$ values, they must also have the same $\boldsymbol{\beta}$ values
Write $\alpha \rightarrow \boldsymbol{\beta}$, read $\alpha$ functionally determines $\beta$, or $\boldsymbol{\beta}$ is functionally dependent on $\alpha$.
FD is actually a many-to-one relationship between $A$ and $B$
$\mathrm{R}(\mathrm{A}, \mathrm{B}, \mathrm{C}, \mathrm{D}, \mathrm{E}, \mathrm{F}, \mathrm{G}, \mathrm{H}$,
c

B
$\left(\mathrm{A}_{1}, \mathrm{~B}_{1}, \mathrm{C}_{1}, \mathrm{D}_{1}, \mathrm{E}_{1}, \mathrm{~F}_{1}\right) \quad \rightarrow\left(\mathrm{I}_{1}, \mathrm{~J}_{1}, \mathrm{~K}_{1}, \mathrm{~L}_{1}, \mathrm{M}_{1}\right)$

## Example 2

Let $R$ be the table Student (studID, studLastName, credits, status, socSecNbr)

| studID | studLastName | credits | status | socSecNbr |
| :--- | :--- | :--- | :--- | :--- |
| S1001 | Smith | 90 | Senior | 100222500 |
| S1003 | Jones | 95 | Senior | 222333444 |
| S1006 | Lee | 15 | Freshman | 088111222 |
| S1010 | Burns | 63 | Junior | 099111222 |
| S1060 | Jones | 25 | Freshman | 064624123 |

FDs in $R$ include
\{studID\} $\rightarrow$ \{studLastName\}, but not the reverse
\{studID\} $\rightarrow$ \{studLastName, credits, status, socSecNbr, stuld\}
\{socSecNbr\} $\rightarrow$ \{studID, studLastName, credits, status, socSecNbr\}
$\{$ credits $\} \rightarrow$ \{status $\},$ but not $\{$ status $\} \rightarrow$ \{credits $\}$

We say that the functional dependency $X \rightarrow Y$ is trivial if set $\{Y\}$ is a subset of set \{X\}
Example 3: If $A$ and $B$ are attributes of $R$,

- $\{A\} \rightarrow\{A\}$
- $\{A, B\} \rightarrow\{A\}$
- $\{A, B\} \rightarrow\{B\}$
- $\{A, B\} \rightarrow\{A, B\}$
are all trivial FDs
Keys
- Superkey - functionally determines all attributes in a relation
- Candidate key - superkey that is a minimal identifier (no extraneous attributes)
- Primary key - candidate key actually used
- Primary key has no-null constraint and uniqueness constraint
- Should also enforce uniqueness and no-null rule for candidate keys

In a relation $R$, the set of attributes $\beta$ is fully functionally dependent on set of attributes $\alpha$ of $R$

- if $\beta$ is functionally dependent on $\alpha$
- but not functionally dependent on any proper subset of $\alpha$
$\alpha$ is the smallest determinant for $\beta$. This means every attribute in $\alpha$ is needed to functionally determine $\beta$

## Example 3.

In table Student1(courseNo, studID, studLastName, facID, schedule, room, grade) some functional dependency are:
\{courseNo, studID\} $\rightarrow$ \{studLastName\}
\{courseNo, studID\} $\rightarrow$ \{facID\}
\{courseNo, studID\} $\rightarrow$ \{schedule\}
\{courseNo, studID\} $\rightarrow$ \{room $\}$
\{courseNo, studID\} $\rightarrow$ \{grade $\}$
courseNo $\rightarrow$ facID **partial FD
courseNo $\rightarrow$ schedule **partial FD
courseNo $\rightarrow$ room ** partial FD
studID $\rightarrow$ studLastName ** partial FD

A relation is in $2 N F$ if it is in $1 N F$ and all the non-key attributes are fully functionally dependent on the key.

- No non-key attribute is FD on just part of the key
- If key has only one attribute, and $R$ is $1 N F, R$ is automatically $2 N F$

## 1NF to 2NF

## Solve partial functional dependency

- Identify each partial FD
- Remove the attributes that depend on each of the determinants so identified
- Place these determinants in separate relations along with their dependent attributes
- In original relation keep the composite key and any attributes that are fully functionally dependent on all of it
- Even if the composite key has no dependent attributes, keep that relation to connect logically the others

## Example 4.

Student1 (courseNo, studID, studLastName, facID, schedule, room, grade)

FDs grouped by determinant:
\{courseNo\} $\rightarrow$ \{courseNo, facID, schedule, room\}
\{stuld\} $\rightarrow$ \{studID, studLastName\}
$\{$ courseNo, studID\} $\rightarrow$ \{courseNo, studID, facID, schedule, room, studLastName, grade\}

Replace Student1 by tables grouped by determinants:
Course (courseNo, facID, schedule, room)
Student2(studID, studLastName)
Student3( courseNo, studID, grade)

## Example 5.

Given the table R ( $\underline{A}, \mathrm{~B}, \mathrm{C}, \mathrm{D}, \mathrm{E}$ ).

$$
R(A, B, C, D, E) \quad \text { key } A, B
$$

$\mathrm{A} \longrightarrow \mathrm{D}$
$\mathrm{A}, \mathrm{B} \longrightarrow \mathrm{C}$
$\mathrm{A}, \mathrm{B} \longrightarrow \mathrm{D}$
$\mathrm{A}, \mathrm{B} \longrightarrow \mathrm{E}$

We replace $R$ by the tables R1 and R2

R1 ( $\underline{A}, \mathrm{C}, \mathrm{D}$ ) key A

and
R2 ( $\mathrm{A}, \mathrm{B}, \mathrm{E})$ key (A, B)

Example 6.
Given the table R ( $\underline{A}, \mathrm{~B}, \mathrm{C} . \mathrm{D}, \mathrm{E}$ )
$R(\underline{A}, B, C, D, E) \quad$ key $A, B$
$A, B \rightarrow C$
A, B $\rightarrow$ D
A, $B \rightarrow$ E
$\mathrm{A} \rightarrow \mathrm{C}$
$\mathrm{A} \rightarrow \mathrm{D}$
$B \rightarrow E$
Replace R by R1 and R2
R1 ( A, C, D ) key A

R2 (B, E ) key B

Example 7.

Given R (Code-Supplier, Code-Product, Quantity, Name-Supplier)

| Code-Supplier | Code-Product | Quantity | Name-Supplier |
| :---: | :---: | :---: | :---: |
| F1 | P1 | 10 | TEK |
| F1 | P2 | 20 | TEK |
| F1 | P3 | 30 | TEK |
| F2 | P2 | 12 | SONY |
| F2 | P4 | 10 | SONY |
| F3 | P3 | 12 | BLII |

## FDs

(Code-Supplier, Code-Product) $\rightarrow$ Quantity
(Code-Supplier, Code-Product) $\rightarrow$ Name-Supplier
Code-Supplier $\rightarrow$ Name-Supplier
Replace R by tables R1 and R2.
R1

| Code-Supplier | Code -Product | Quantity |
| :---: | :---: | :---: |
| F1 | P1 | 10 |
| F1 | P2 | 20 |
| F1 | P3 | 30 |
| F2 | P2 | 12 |
| F2 | P4 | 10 |
| F3 | P3 | 12 |

## R2

| Code- Supplier |  |
| :---: | :---: |
| F1 | TEK |
| F2 | SONY |
| F3 | BLII |

## How is better, R or R1 and R2?

Add
We like to add a new supplier without knowing its products

- Can't add in R
- We can add it in $\mathrm{R}_{2}$.

Delete
Suppose the supplier F3 stops to supply the product P3.

- Delete tuple for F3, P3 from R. We loose all information concerning

123
Mariana Kant - Relational model Normalization

- Delete F3, P3 in R1. No lost of information about F3.

## Update

Change the name of supplier F1 to XTER.

- Scan all tuples in R to find and update F1.
- Change one single tuple in R2 (key Code-Supplier)._

Transitive dependency
If $A, B$, and $C$ are attributes of table $R$, such that $A \rightarrow B$, and $B \rightarrow C$, then $C$ is transitively dependent on $A$

Example 8
Student (studID, studLastName, major, credits, status)
FD:
credits $\rightarrow$ status
studID $\rightarrow$ credits
by transitivity it implies studID $\rightarrow$ status
Transitive dependencies cause update, insertion, deletion anomalies.

## 3NF Third Normal Form

A relation is in third normal form (3NF) if whenever a non-trivial functional dependency $X \rightarrow A$ exists, then either $X$ is a superkey or $A$ is a member of some candidate key

- To be 3NF, relation must be 2NF and have no transitive dependencies
- No non-key attribute determines another non-key attribute. Here key includes "candidate key"

## 2NF to 3NF

Solve transitive dependency

- Remove the dependent attribute from the relation
- Create a new table with the dependent attribute and its determinant
- Keep the determinant in the original table

Example: Given the relation $R(\underline{A}, B, C)$.
$R(A, B, C) \quad$ key $A$
$A \rightarrow B$
$\mathrm{A} \rightarrow \mathrm{C}$
$B \rightarrow C$
B not $\rightarrow \mathrm{A}$
Replace $R$ by
R1 ( $\mathrm{A}, \mathrm{B}$ ) key A
R2(B, C) key B

Example 9 : Given the relation $R$ (\#Part, Code_Tax, Tax).

| \# Part | Code_Tax | Tax |
| :---: | :---: | :---: |
| P1 | 1 | $18.6 \%$ |
| P2 | 1 | $18.6 \%$ |
| P3 | 2 | $33 \%$ |
| P4 | 1 | $18.6 \%$ |
| P5 | 1 | $18.6 \%$ |

Replace $R$ by $R_{1}$ (\# Part, Code_Tax) and $R_{2}$ ( Code_Tax, Tax)
$\mathrm{R}_{1}$

| \# Part | Code_Tax |
| :--- | :--- |
| P1 | 1 |
| P2 | 1 |
| P3 | 2 |
| P4 | 1 |
| P5 | 1 |

$\mathrm{R}_{2}$

| Code_Tax | Tax |
| :---: | :---: |
| 1 | $18.6 \%$ |
| 2 | $33 \%$ |

## How is better, R or R1 and R2?

## Add

We like to add a new $8.6 \%$ tax with code 3

- No way to add it in R. The key is not defined for only tax code (?, 3, 8.6\%).
- New tuple in R2 with Code_Tax 3.

## Delete

Delete part $\mathrm{P}_{3}$

- Delete P3 in R. BUT we loose the information concerning the tax (33\%) for Code_Tax =2.
- Delete P3 in R1. No lost of information.

## Update

Change Tax at $17 \%$ for Code_Tax $=1$.

- Scan all tuples of R to find tuples having Code_Tax=1 to make the update.
- One tuple update in $\mathrm{R}_{2}$.

Observation:
The relation $R(A, B, C)$ has to candidate keys $A$ and $B, A$ is the primary key.

A key
This table is in 3NF.
Example 10
Student (studID, studLastName, major, credits, status)
with FD credits $\rightarrow$ status

- Remove the dependent attribute, status, from the relation
- Create a new table with the dependent attribute and its determinant, credits
- Keep the determinant in the original table

Student2 (studID, studLastName, major, credits)
Stats (credits, status)

## BCNF Boyce-Codd Normal Form

A relation is in Boyce/Codd Normal Form (BCNF) if whenever a non-trivial functional dependency $X \rightarrow A$ exists, then $X$ is a superkey
If there is just one single candidate key, the forms are equivalent

## 3NF to BCNF

## Check and solve determinants

Look in a 3NF table for:

- two or more composites candidates keys
- two candidates keys having common attributes

1. identify all candidate keys in $R$.
2. identify all FD in $R$ R.
3. if there exists determinants which are not candidate keys, replace $R$ by $R_{1}$ and $\mathbf{R}_{\mathbf{2}}$ and put in $\mathbf{R}_{\mathbf{2}}$ the determinants and the corresponding tuples
Example 11
Given the table R (M, N, O, P)
$(\mathrm{M}, \mathrm{N}) \rightarrow \mathrm{O}$
$(\mathrm{M}, \mathrm{N}) \rightarrow \mathrm{P}$
$\mathrm{P} \rightarrow \mathrm{M}$
Replace $R$ by
$R_{1}(\underline{M}, \mathrm{~N}, \mathrm{O})$
$\mathrm{R}_{2}(\mathrm{P}, \mathrm{M})$
$\mathrm{R}_{3}(\underline{\mathrm{~N}, \mathrm{P}})$
4. If there are common attributes between candidate keys replace R by R1 and R2 such as the common attribute is in only one table.

## Example 12.

The suppliers' names are unique. There are two candidate keys.
(Supplierld, Productld) and (SupplierName, Productld)
and there are functional dependencies between parts of the candidate keys.
SuppilerID $\rightarrow$ SupplierName
SupplierName $\rightarrow$ SupplierID
