

Day 23

Representing and Reasoning About Space (Chapter 6)

# Introduction

- ▶ representing the environment
  - ▶ affects how the robot reasons about its environment
- ▶ how should space be represented?
  - ▶ map representation, how to map, planning on a map
- ▶ how to represent the robot?
  - ▶ configuration space
- ▶ how the robot can reason with respect to its representation of space

# Representing Space

- ▶ many tasks require a representation of the robot's environment (a map)
  - ▶ but many complex tasks can be accomplished without an explicit map (e.g., Roomba)
- ▶ in addition to representing places in the environment, the map can include other information
  - ▶ “Here there be dragons!”

# Representing Space

- ▶ at least 3 different classes of task typically require a map
  1. to establish what parts of the environment are free for navigation
    - ▶ called the free space
    - ▶ path planning
  2. to recognize regions or locations
  3. to recognize specific objects

# Spatial Decomposition

- ▶ represent space itself, rather than the objects in it, using discrete samples
- ▶ many ways to perform the sampling, but the simplest is to use a grid

uniform sampling

□ free space  
■ occupied

# Uniform Sampling

- ▶ very general representation
  - ▶ grid locations can represent anything
- ▶ if something moves then the representation does not change dramatically
- ▶ limited by grid resolution
  - ▶ large cell sizes give a coarse representation
  - ▶ small cell sizes are storage intensive
    - ▶ football pitch (soccer field) at  $1\text{ cm}^2$  resolution
      - $105\text{m} \times 68\text{m} \times 100 \times 100 = 71,400,000$  cells
    - ▶ 3D is much worse

# Recursive Hierarchical Representations

- ▶ storage space can be conserved by observing that free space cells and occupied cells tend to cluster
  - ▶ group the clusters into larger cells
- ▶ quadtree
  - ▶ recursively subdivided space into 4 equal-sized cells until every cell is either uniformly free or uniformly occupied
    - ▶ or some threshold resolution is achieved

# Quadtree Decomposition

□ free space  
■ occupied

# Quadtree Decomposition

□ free space  
■ occupied

# Quadtree Decomposition

□ free space  
■ occupied

# Quadtree Decomposition

□ free space  
■ occupied

# Quadtree Decomposition

□ free space  
■ occupied

# Quadtree Decomposition

- ▶ worst case performance
  - ▶ same as uniform subdivision
- ▶ if most of the space is occupied or freespace then the representation is compact
- ▶ generalizes to N dimensions
- ▶ representation can change dramatically if objects move even a small amount

# Geometric Representations

- ▶ discrete geometric primitives
  - ▶ points
  - ▶ lines, line segments, polylines
  - ▶ circles, ellipses
  - ▶ polyhedra
  - ▶ splines

# Representing the Robot

- ▶ to create motion plans for the robot, we must account for the position and size of the robot
  - ▶ we must be able to specify the location of every point on the robot
- ▶ in robotics, the configuration space is a fundamental concept in motion planning

# Configuration Space

- ▶ **configuration**
  - ▶ a complete specification of the position of every point of the robot
- ▶ **configuration space (C-space)**
  - ▶ the space of all possible configurations of the robot

# Example: Point Robot

- ▶ consider a point robot that can translate (but not rotate) in the infinite plane
- ▶ configuration
  - ▶ just the location

$$q = (x, y)$$

- ▶ configuration space
  - ▶  $\mathbb{R}^2$  (the Cartesian plane)

# Example: Circular Robot

- ▶ consider a circular robot of radius  $R$  that can translate (but not rotate) in the infinite plane
- ▶ configuration?
  - ▶ suppose the center of the robot has position  $(x, y)$
  - ▶ then the points on the robot are given by

$$R(x, y) = \{(x', y') \mid (x - x')^2 + (y - y')^2 \leq r^2\}$$

- ▶ so  $(x, y)$  is sufficient to describe the configuration of the robot
- ▶ configuration space
  - ▶  $\mathbb{R}^2$  (the Cartesian plane)

# Example: 2-Link Planar Arm

- ▶ consider a 2-link planar arm with no joint angle limits
- ▶ configuration
  - ▶ joint angles

$$q = (\theta_1, \theta_2)$$

# Example: 2-Link Planar Arm

- ▶ configuration space

- ▶ each angle corresponds to a point on a unit circle

- ▶ configuration space is a torus, which can be cut and flattened onto the plane

# Obstacles in C-Space

- ▶ obstacles in the environment may limit the set of possible configurations of the robot
  - ▶ let  $B_i$  be an obstacle in the environment
  - ▶ let  $C$  be the configuration space of the robot
  - ▶ let  $A(q)$  be the portion of space occupied by the robot when it is in configuration  $q$
  - ▶ then  $CB_i$  is the configuration space representation of the obstacle (C-obstacle) defined as

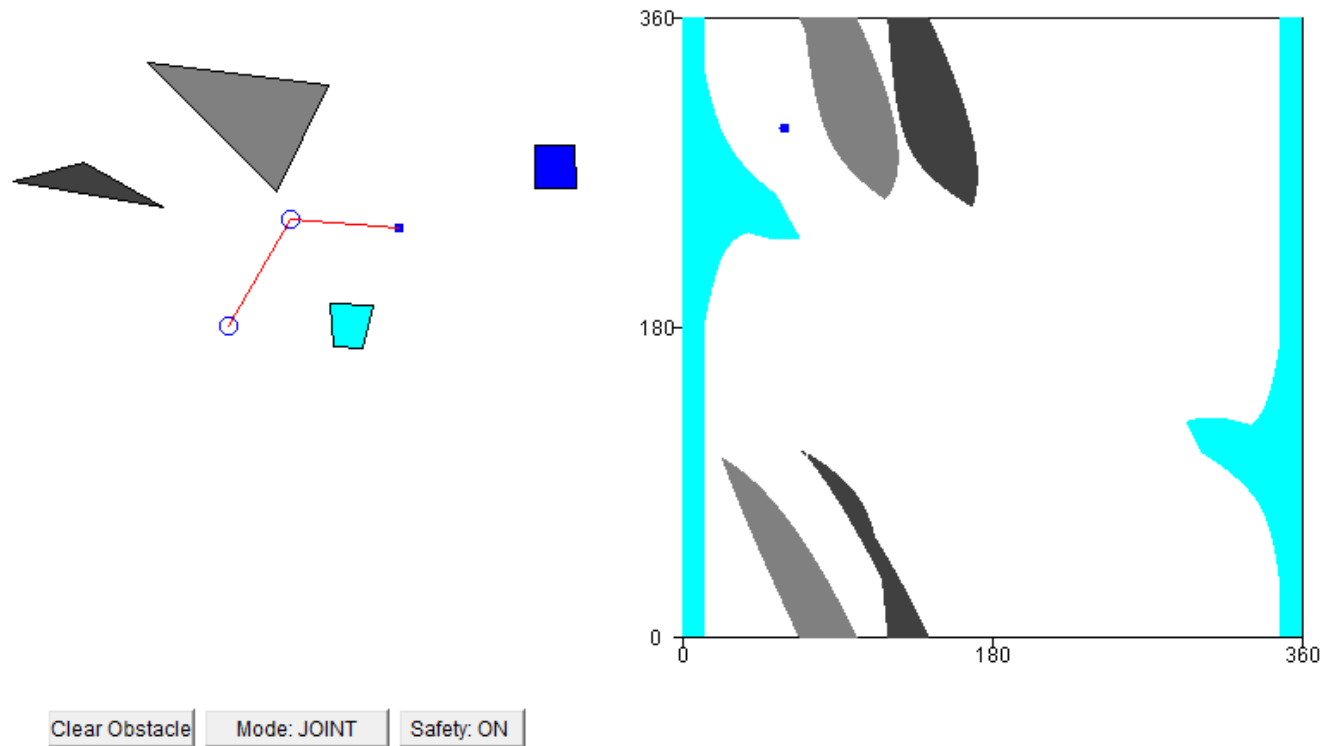

$$CB_i = \{q \in C \mid A(q) \cap B_i \neq \emptyset\}$$

# Example: 2-Link Planar Robot

## Planar Robot Simulator with Obstacle Avoidance (Configuration Space)

(Requires Java enabled browser: Please allow 60-200 seconds to load)

# Example: Circular Robot

- ▶ the free configuration space for a circular robot can be found by tracing the obstacles in the workspace with the robot

workspace

● robot (now a point!)

C-space

# Example: Circular Robot
