
Link-State and Distance Vector Routing Examples

CPSC 441

University of Calgary

Link-State (LS) Routing Algorithm

Dijkstra's algorithm

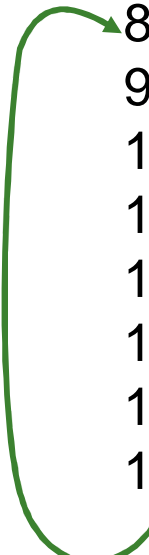

- topology and link costs known to all nodes
 - accomplished via “link state broadcast”
 - all nodes have same info
- computes least cost paths from one node (source) to all other nodes
 - gives **forwarding table** for that node
- iterative: after k iterations, know least cost path to k destination nodes

Notation:

- $c(x,y)$: **link** cost from node x to y ; set to ∞ if x and y are not direct neighbors
- $D(v)$: current value of cost of **path** from source to dest. v
- $p(v)$: v 's predecessor node along path from source to v
- N' : set of nodes whose least cost path is definitively known

Dijkstra's Algorithm

```
1 Initialization (u = source node):  
2 N' = {u} /* path to self is all we know */  
3 for all nodes v  
4   if v adjacent to u  
5     then D(v) = c(u,v) /* assign link cost to neighbours */  
6   else D(v) = ∞  
7  
8 Loop  
9   find w not in N' such that D(w) is a minimum  
10  add w to N'  
11  update D(v) for all v adjacent to w and not in N' :  
12    D(v) = min( D(v), D(w) + c(w,v) )  
13  /* new cost to v is either old cost to v or known  
14   shortest path cost to w plus cost from w to v */  
15 until all nodes in N'
```

Textbook – Problem 4.21 – x is source

| Step | N' | $D(s),p(s)$ | $D(t),p(t)$ | $D(u),p(u)$ | $D(v),p(v)$ | $D(w),p(w)$ | $D(y),p(y)$ | $D(z),p(z)$ |
|------|------|-------------|-------------|-------------|-------------|-------------|-------------|-------------|
| 0 | x | ∞ | ∞ | ∞ | 3,x | 1,x | 6,x | ∞ |

Initialization:

- Store source node x in N'
- Assign link cost to neighbours (v,w,y)
- Keep track of predecessor to destination node

Textbook – Problem 4.21 – x is source

Node and its minimum cost are colour-coded in each step

| Step | N' | $D(s),p(s)$ | $D(t),p(t)$ | $D(u),p(u)$ | $D(v),p(v)$ | $D(w),p(w)$ | $D(y),p(y)$ | $D(z),p(z)$ |
|------|------|-------------|-------------|-------------|-------------|-------------|-------------|-------------|
| 0 | x | ∞ | ∞ | ∞ | 3,x | 1,x | 6,x | ∞ |
| 1 | xw | ∞ | ∞ | 4,w | 2,w | | 6,x | ∞ |

Loop – step 1:

- For all nodes not in N' , find one that has minimum cost path (1)
 - Add this node (w) to N'
 - Update cost for all neighbours of added node that are not in N'
- repeat until all nodes are in N'

Textbook – Problem 4.21 – x is source

Node and its minimum cost are colour-coded in each step

| Step | N' | $D(s),p(s)$ | $D(t),p(t)$ | $D(u),p(u)$ | $D(v),p(v)$ | $D(w),p(w)$ | $D(y),p(y)$ | $D(z),p(z)$ |
|------|---------|-------------|-------------|-------------|-------------|-------------|-------------|-------------|
| 0 | x | ∞ | ∞ | ∞ | 3,x | 1,x | 6,x | ∞ |
| 1 | xw | ∞ | ∞ | 4,w | 2,w | | 6,x | ∞ |
| 2 | xwv | ∞ | 11,v | 3,v | | | 3,v | ∞ |
| 3 | xwvu | 7,u | 5,u | | | | 3,v | ∞ |
| 4 | xwvuy | 7,u | 5,u | | | | | 17,y |
| 5 | xwvuyt | 6,t | | | | | | 7,t |
| 6 | xwvuyts | | | | | | | 7,t |

Textbook – Problem 4.21 – x is source

We can now build x's forwarding table. E.g. the entry to s will be constructed by looking at predecessors along shortest path: 6,t → 5,u → 3,v → 2,w (direct link) So forward to s via w

| Step | N' | $D(s),p(s)$ | $D(t),p(t)$ | $D(u),p(u)$ | $D(v),p(v)$ | $D(w),p(w)$ | $D(y),p(y)$ | $D(z),p(z)$ |
|------|---------|-------------|-------------|-------------|-------------|-------------|-------------|-------------|
| 0 | x | ∞ | ∞ | ∞ | 3,x | 1,x | 6,x | ∞ |
| 1 | xw | ∞ | ∞ | 4,w | 2,w | | 6,x | ∞ |
| 2 | xwv | ∞ | 11,v | 3,v | | | 3,v | ∞ |
| 3 | xwvu | 7,u | 5,u | | | | 3,v | ∞ |
| 4 | xwvuy | 7,u | 5,u | | | | | 17,y |
| 5 | xwvuyt | 6,t | | | | | | 7,t |
| 6 | xwvuyts | | | | | | | 7,t |

Distance Vector Routing

- Based on Bellman-Ford Equation

- Define

$d_x(y) :=$ cost of least-cost path from x to y

$c(x,v) :=$ cost of direct link from x to v

- Then, for all v that are neighbours of x

$$d_x(y) = \min_v \{ c(x,v) + d_v(y) \}$$

Bellman-Ford Equation Example

Consider a path from u to z

By inspection, $d_v(z) = 5$, $d_x(z) = 3$, $d_w(z) = 3$

B-F equation says:

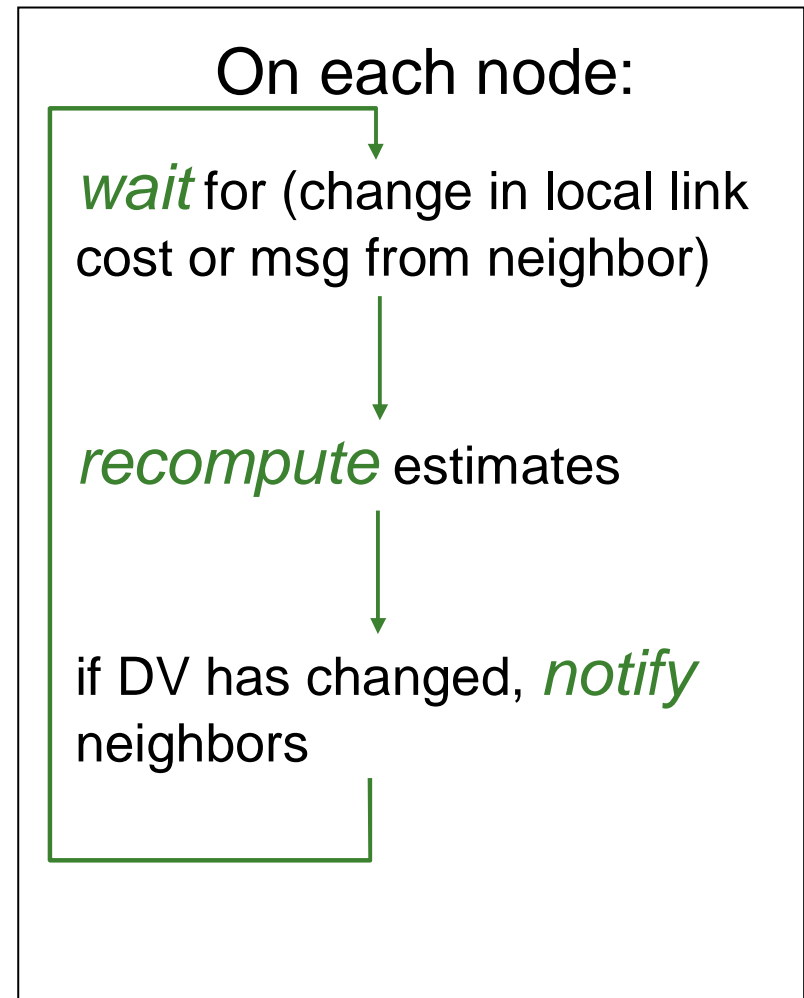

$$\begin{aligned} d_u(z) &= \min \{ c(u,v) + d_v(z), \\ &\quad c(u,x) + d_x(z), \\ &\quad c(u,w) + d_w(z) \} \\ &= \min \{ 2 + 5, \\ &\quad 1 + 3, \\ &\quad 5 + 3 \} = 4 \end{aligned}$$

Node that achieves minimum is next
hop in shortest path → entry in forwarding table

Distance Vector Algorithm

Basic idea:

- Nodes keep vector (DV) of least costs to other nodes
 - These are estimates, $D_x(y)$
- Each node periodically sends its own DV to neighbors
- When node x receives DV from neighbor, it keeps it and updates its own DV using B-F:
$$D_x(y) \leftarrow \min_v \{c(x,v) + D_v(y)\}$$
for each node $y \in N$
- Ideally, the estimate $D_x(y)$ *converges to the actual least cost $d_x(y)$*

node x table

| | | cost to | | |
|------|---|----------|----------|----------|
| | | x | y | z |
| from | x | 0 | 2 | 7 |
| | y | ∞ | ∞ | ∞ |
| | z | ∞ | ∞ | ∞ |

node y table

| | | cost to | | |
|------|---|----------|----------|----------|
| | | x | y | z |
| from | x | ∞ | ∞ | ∞ |
| | y | 2 | 0 | 1 |
| | z | ∞ | ∞ | ∞ |

node z table

| | | cost to | | |
|------|---|----------|----------|----------|
| | | x | y | z |
| from | x | ∞ | ∞ | ∞ |
| | y | ∞ | ∞ | ∞ |
| | z | 7 | 1 | 0 |

Step 1: Initialization

Initialize costs of direct links

Set to ∞ costs from neighbours

► time

$$D_x(y) = \min\{c(x,y) + D_y(y), c(x,z) + D_z(y)\}$$

$$= \min\{2+0, 7+1\} = 2$$

$$D_x(z) = \min\{c(x,y) + D_y(z), c(x,z) + D_z(z)\}$$

$$= \min\{2+1, 7+0\} = 3$$

node x table

| | | cost to | | |
|------|---|---------|---|---|
| | | x | y | z |
| from | x | 0 | 2 | 7 |
| | y | ∞ | ∞ | ∞ |
| | z | ∞ | ∞ | ∞ |

| | | cost to | | |
|------|---|---------|---|---|
| | | x | y | z |
| from | x | 0 | 2 | 3 |
| | y | 2 | 0 | 1 |
| | z | 7 | 1 | 0 |

node y table

| | | cost to | | |
|------|---|---------|---|---|
| | | x | y | z |
| from | x | ∞ | ∞ | ∞ |
| | y | 2 | 0 | 1 |
| | z | ∞ | ∞ | ∞ |

node z table

| | | cost to | | |
|------|---|---------|---|---|
| | | x | y | z |
| from | x | ∞ | ∞ | ∞ |
| | y | ∞ | ∞ | ∞ |
| | z | 7 | 1 | 0 |

Step 2: Exchange DV and iterate

- In first iteration, node x saves neighbours' DVs
- Then, it checks path costs to all nodes using received DVs
- E.g. new cost $D_x(z)$ is obtained by adding costs marked red

► time

In similar fashion, algorithm proceeds until all nodes have updated tables

node x table

| | | cost to | | |
|------|---|----------|----------|----------|
| | | x | y | z |
| from | x | 0 | 2 | 7 |
| | y | ∞ | ∞ | ∞ |
| | z | ∞ | ∞ | ∞ |

node y table

| | | cost to | | |
|------|---|----------|----------|----------|
| | | x | y | z |
| from | x | ∞ | ∞ | ∞ |
| | y | 2 | 0 | 1 |
| | z | ∞ | ∞ | ∞ |

node z table

| | | cost to | | |
|------|---|----------|----------|----------|
| | | x | y | z |
| from | x | ∞ | ∞ | ∞ |
| | y | ∞ | ∞ | ∞ |
| | z | 7 | 1 | 0 |

| | | cost to | | |
|------|---|---------|---|---|
| | | x | y | z |
| from | x | 0 | 2 | 3 |
| | y | 2 | 0 | 1 |
| | z | 7 | 1 | 0 |

| | | cost to | | |
|------|---|---------|---|---|
| | | x | y | z |
| from | x | 0 | 2 | 7 |
| | y | 2 | 0 | 1 |
| | z | 7 | 1 | 0 |

| | | cost to | | |
|------|---|---------|---|---|
| | | x | y | z |
| from | x | 0 | 2 | 7 |
| | y | 2 | 0 | 1 |
| | z | 3 | 1 | 0 |

| | | cost to | | |
|------|---|---------|---|---|
| | | x | y | z |
| from | x | 0 | 2 | 3 |
| | y | 2 | 0 | 1 |
| | z | 3 | 1 | 0 |

| | | cost to | | |
|------|---|---------|---|---|
| | | x | y | z |
| from | x | 0 | 2 | 3 |
| | y | 2 | 0 | 1 |
| | z | 3 | 1 | 0 |

| | | cost to | | |
|------|---|---------|---|---|
| | | x | y | z |
| from | x | 0 | 2 | 3 |
| | y | 2 | 0 | 1 |
| | z | 3 | 1 | 0 |

▶ time

Distance Vector: link cost changes

Link cost changes:

- node detects local link cost change
- updates routing info, recalculates distance vector
- if DV changes, notify neighbors

At time t_0 , y detects the link-cost change, updates its DV, and informs its neighbors.

“good
news
travels
fast”

At time t_1 , z receives the update from y and updates its table. It computes a new least cost to x and sends neighbors its DV.

At time t_2 , y receives z 's update and updates its distance table. y 's least costs do not change and hence y does *not* send any message to z .

Distance Vector: link cost changes

Link cost changes:

- bad news travels slow - “count to infinity” problem!
- When y detects cost change to 60, it will update its DV using the z’s cost to x, which is 5 (via y), to obtain an incorrect new cost to x of 6, over the path $y \rightarrow z \rightarrow y \rightarrow x$ that has a loop
- 44 iterations before algorithm stabilizes, while y and z exchange updates

Poisoned reverse:

- If Z routes through Y to get to X :
 - Z tells Y its (Z’s) distance to X is infinite (so Y won’t route to X via Z)
- Will this completely solve the problem?
