

## *Appearance of Objects*

- object appearance depends on three factors:
  - ◆ lighting
  - ◆ material properties
  - ◆ viewer properties
- for the most part, graphics techniques do not account for the properties of the viewer
  - ◆ example: for the synthetic camera, properties of film are not modeled
  - ◆ example: for a human observer, properties of human visual system (eye and brain) are not modeled

## *Human Vision*

- it is useful (and interesting) to study human vision to understand the generation and appearance of computer images
- vision is the inverse problem of graphics
  - ◆ graphics: how do we describe the 3D (4D if we consider time) world to produce a 2D image?
  - ◆ vision: given a 2D image, what can we infer about the 3D/4D world?
- the eyes and brain comprise the human visual system
  - ◆ we will only study the eye

## *Structure of the Eye*

## *Structure of Eye (cont)*

### ■ cornea

- ◆ clear coating over front of eye
- ◆ two major purposes:
  - ◆ protects internal structure
  - ◆ focusing of light (cornea is strongest focusing element in the eye)

### ■ iris

- ◆ colored annulus between cornea and lens
- ◆ changes the size of the pupil to allow more or less light into the eye

## *Structure of the Eye (cont)*

### ■ lens

- ◆ clear elastic focusing element
- ◆ muscles stretch and compress the lens to help focus light (elasticity diminishes with age)

### ■ retina

- ◆ thin layer of cells covering approximately 200 degrees on the back of the eye
- ◆ two types of photosensitive cells in retina:
  - ◆ cones: sensitive to color light
  - ◆ rods: sensitive to light intensity only (not color) but 10 times more sensitive than cones

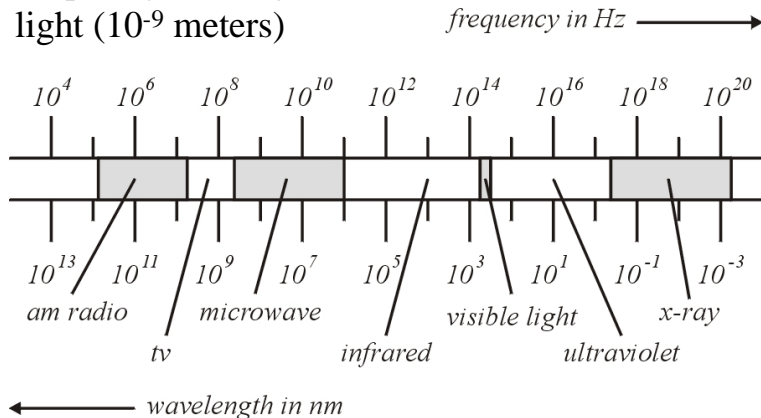

## *Structure of the Eye (cont)*

### ■ fovea

- ◆ very small region of the retina with the densest collection of cone cells (147,000 cones/mm)
  - ◆ some hawks have 1,000,000 cells in the same area (can see a small animal at a distance where a human could not even see the hawk)
- ◆ visual field is centered on fovea
- ◆ rods start to appear at the edge of the fovea and increase rapidly in density away from fovea
  - ◆ night vision is often better slightly away from the center of the visual field

## *The Nature of Light*

- light is an electromagnetic phenomenon (like radio waves, microwave, x-rays, etc)
- waves are characterized by wavelength (or frequency) usually measured in nanometers for light ( $10^{-9}$  meters)

## *Visible Spectrum*

[www.handprint.com/HP/WCL/color1.html](http://www.handprint.com/HP/WCL/color1.html)

- visible spectrum approximately 400-700nm
- light does not have color
  - ◆ the sensation of color is perceived
- color perception starts with cone cells

## *Tristimulus Theory*

- 3 different cone cells respond to certain regions of the visible spectrum

## *Tristimulus Theory (cont)*

- only have 3 (?) different types of cone cells
  - ◆ this suggests that a properly blended combination of three different colors can reproduce any color light we perceive
  - ◆ mantis shrimp has 10 different color receptors
- a good choice of colors is red, green, and blue
- if you take a red, green, and blue light can you match any color light?
  - ◆  $C = rR + gG + bB$  ?

## *Tristimulus Theory (cont)*

- many target color lights cannot be matched
  - ◆ what if we add red light to the target light?
    - ◆  $C + rR = gG + bB$ 
      - this works!
  - ◆ mathematically same as adding a negative amount of red light
    - ◆  $C = -rR + gG + bB$
- picture of color-matching functions  $r$ ,  $g$ ,  $b$  in Hill Figure 12.6

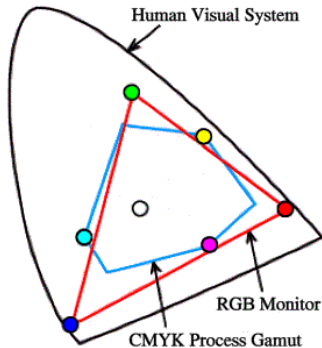

## *CIE Color Matching Functions*

- Commission Internationale de L'Eclairage (CIE) defined the standard observer (1931)
- invented three primary color lights (X, Y, and Z) that when added in positive amounts can match any perceivable color light
  - ◆  $C = xX + yY + zZ$
  - ◆ Hill Figure 12.8

# CIE Chromaticity Diagram

- coefficients  $x$ ,  $y$ ,  $z$  define a 3D color space
- a 2D slice of this space yields the CIE chromaticity diagram (Hill Figure 12.10)

[viz.cac.psu.edu/sem\\_notes/color\\_2d/html/working\\_with\\_color.html](http://viz.cac.psu.edu/sem_notes/color_2d/html/working_with_color.html)

## *RGB Color Space*

- most common color space in graphics is red-green-blue (RGB) color space
  - ◆ reason: easy to display on color monitors (which use red, green, and blue phosphors)
- $C = rR + gG + bB$  where
$$0 \leq r \leq 1, \quad 0 \leq g \leq 1, \quad 0 \leq b \leq 1$$
- additive color space

C cyan  
Y yellow  
M magenta  
W white

## *RGB Color Space (cont)*

■ in 3D r, g, b form a color cube

## *RGB Color Space (cont)*

■ some rgb values for colors

color	r	g	b	color	r	g	b
black	0	0	0	cyan	0	1	1
white	1	1	1	magenta	1	0	1
gray	0.5	0.5	0.5	orange	1	0.65	0
red	1	0	0	navy	0	0	0.5
green	0	1	0	sky blue	0.53	0.81	0.98
blue	0	0	1	khaki	0.94	0.90	0.55
yellow	1	1	0	maroon	0.69	0.19	0.38

■ note that this is not an intuitive color space!

## *CMY and CMYK Color Spaces*

- most common printer color spaces are cyan-magenta-yellow (CMY) and CMYK (CMY plus black)
- C, M, Y, and K are not lights but filters of light
  - ◆ cyan filters out red
  - ◆ magenta filters out green
  - ◆ yellow filters out blue
  - ◆  $(c, m, y) = (1, 1, 1) - (r, g, b)$
- subtractive color space
  - ◆ start with white light and subtract red, green, and blue light using cyan, magenta, and yellow filters

## *CMY and CMYK Color Spaces (cont)*

- your printer deposits tiny dots of transparent cyan, magenta, and yellow ink
  - ◆ each of these dots acts like a filter
  - ◆ printed images only look correct if printed on white paper and illuminated with white light
- equal amounts of cyan, magenta, and yellow can be replaced with black
  - ◆ conserves the more expensive color inks
    - ◆  $k = \min(c, m, y)$
    - ◆  $(c - k, m - k, y - k, k)$

## *CMY and CMYK Color Spaces (cont)*

■ in 3D c, m, y form a color cube

## *HSV Color Space*

- hue, saturation, value (HSV) is a more intuitive color space than RGB
- hue
  - ◆ the different color sensations
    - ◆ red, green, and blue are different hues
- saturation
  - ◆ purity of color or how far from gray a color is
    - ◆ red is fully saturated (saturation = 1)
    - ◆ pink is less saturated (saturation < 1)
    - ◆ white is zero saturation (saturation = 0)
  - ◆ no mixture of three primaries is fully saturated

## *HSV Color Space (cont)*

- value

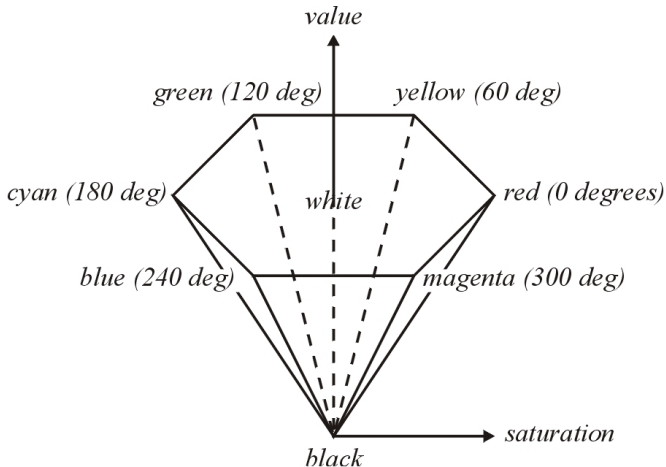

- ◆ the sensation of light and dark colors
- ◆ white has a value of 1 and black has a value of 0

- easier for a human to choose colors

- ◆ pick the color family (red, green, yellow, etc)
- ◆ pick the purity or strength of the color
- ◆ pick the lightness of the color

## *HSV Color Space (cont)*

- hue is measured in degrees around the circle
- forms a hexcone in space

## *Color in OpenGL*

- OpenGL only supports RGB and RGBA
  - ◆ we'll study RGBA a little later
- whenever an object is drawn, it is drawn with the current color
  - ◆ set color, draw, set color, draw, etc
- specify colors using
  - `void glColor3f(float red, float green, float blue)`
- sets the current color to (red, green, blue) where the values of red, green, and blue are clamped to between 0.0f and 1.0f

## *Color in OpenGL (cont)*

- can set the color per vertex

- ◆ OpenGL will interpolate color between vertices

```
glBegin( GL_QUADS );  
  glColor3f( 1.0f, 0.0f, 0.0f ); // red  
  glVertex2f( 0.0f, 1.0f );  
  glVertex2f( 0.0f, 0.0f );  
  glColor3f( 0.0f, 0.0f, 1.0f ); // blue  
  glVertex2f( 1.0f, 0.0f );  
  glVertex2f( 1.0f, 1.0f );  
glEnd();
```

red

blue

## *Interaction of Light With Matter*

- interaction of light with matter is generally not well understood
- a simplified approach is the bidirectional reflection distribution function (BRDF)
  - ◆ an even simpler approach is taken by traditional computer graphics (we'll study this shortly)
- BRDF assumes that light striking a point on the surface leaves the surface from the same point
  - ◆ idea: for *every* direction incident on a point, measure the amount of light leaving the point in *every* direction

## ***BRDF***

- the BRDF is often written as  $R(\lambda, \phi_i, \theta_i, \phi_v, \theta_v)$ 
  - ◆  $\lambda$  is the wavelength (hue) of incident light
  - ◆  $(\phi_i, \theta_i)$  defines the direction to the light source  $L$
  - ◆  $(\phi_v, \theta_v)$  defines the direction to the viewer  $V$
- the BRDF tells us about the ratio of the incoming and reflected light

## *BRDF (cont)*

- for real materials BRDF is usually very complex
  - ◆ need lots of samples from a BRDF to accurately model a surface
  - ◆ from “3D Computer Graphics” by Alan Watt

- need simpler models for most graphics applications

## *Phong Reflection Model*

- most common model in computer graphics
- Hill uses “shading model” which is confusing
- model not based on physical principles
  - ◆ but looks good for plastic-like surfaces
- aside:
  - ◆ physically-based illumination models
    - ◆ Cook-Torrance (see Hill)
    - ◆ He (SIGGRAPH’91)
    - ◆ Oren and Nayar (SIGGRAPH’94)

## *Phong Reflection Model*

- total light intensity at a surface is sum of three components:

$$I_{\text{total}} = I_{\text{amb}} + I_{\text{diff}} + I_{\text{spec}}$$

$I_{\text{amb}}$             ambient intensity

$I_{\text{diff}}$             diffuse intensity

$I_{\text{spec}}$             specular intensity

## *Reflected Ambient Intensity*

- why can you see the bottom of things when light comes from above? why are shadows not absolute black?
  - ◆ because light is reflected from other surfaces
    - ◆ called global illumination
- global illumination is very difficult to model accurately
- ambient intensity is crude approximation of effect of global illumination

## *Reflected Ambient Intensity (cont)*

- assume ambient intensity is constant

- depends on:

- ◆ amount of ambient illumination  $I_a$

- ◆ property of light source

- ◆ material property  $\rho_a$

- ◆ property of object

- ◆ called ambient reflection coefficient

- $\rho_a$  is fraction of ambient intensity reflected by surface

- ◆  $0 \leq \rho_a \leq 1$

- yields the reflected ambient intensity  $I_{amb} = I_a * \rho_a$

## *Reflected Ambient Intensity (cont)*

- picture of spheres lit with ambient light only
  - ◆ ambient reflection coefficient increases from left to right

- makes objects look flat

## *Reflected Diffuse Intensity*

- a diffuse reflector reflects incident light equally in all directions
- obey Lambert's Law:
  - ◆ reflected intensity proportional to  $\cos(\theta)$

- independent of where the viewer is
  - ◆ reflected intensity is the same in all directions

## *Reflected Diffuse Intensity (cont)*

### ■ depends on:

- ◆ light source intensity  $I_s$ 
  - ◆ property of light source(s)
- ◆ material property  $\rho_d$ 
  - ◆ property of object
  - ◆ called diffuse reflection coefficient

### ■ $\rho_d$ is fraction of diffuse intensity reflected by surface

- ◆  $0 \leq \rho_d \leq 1$

### ■ yields the reflected diffuse intensity

$$I_{\text{diff}} = I_s * \rho_d * \text{lambert}$$

## *Reflected Diffuse Intensity (cont)*

- examples of mostly diffuse surfaces:
  - ◆ roughened plastic, chalk, writing paper
- picture of spheres lit with diffuse intensity only
  - ◆ diffuse reflection coefficient increases from left to right

- provides information about shape

## *Reflected Specular Intensity*

- specular intensity models shininess
  - ◆ results in highlights
- most of incident intensity reflected in mirror direction
  - ◆ but some is reflected around the mirror direction
- Phong approximation is pure hack
  - ◆ reflected intensity proportional to  $\cos^f(\phi)$

## Reflected Specular Intensity (cont)

■ how do we compute the mirror direction?

◆ mirror direction

$$\vec{r} = -\vec{s} + 2 \frac{\vec{s} \cdot \vec{n}}{|\vec{n}|^2} \vec{n}$$

■ mirror direction is a bit expensive to compute

◆ we can use the angle  $\beta$  between the normal vector and the halfway vector instead

## *Reflected Specular Intensity (cont)*

### ■ depends on:

- ◆ light source intensity  $I_s$ 
  - ◆ property of light source(s)
- ◆ two material properties
  - ◆ specular reflection coefficient  $\rho_s$
  - ◆  $\rho_s$  is fraction of specular intensity reflected by surface
    - $0 \leq \rho_s \leq 1$
  - ◆ specular reflection exponent  $f$
  - ◆  $f$  controls how fast the highlight decreases
  - ◆ big highlight  $1 \leq f \leq 200$  small highlight

## *Reflected Specular Intensity (cont)*

- using the mirror direction we get:

$$\text{phong} = \max(0, \cos(\phi)) = \max\left(0, \frac{\vec{r} \cdot \vec{v}}{|\vec{r}| |\vec{v}|}\right)$$

- using the halfway vector we get:

$$\text{phong} = \max(0, \cos(\beta)) = \max\left(0, \frac{\vec{h} \cdot \vec{n}}{|\vec{h}| |\vec{n}|}\right)$$

- yields the reflected specular intensity

$$I_{\text{spec}} = I_s * \rho_s * \text{phong}^f$$

## *Reflected Specular Intensity (cont)*

- examples of specular surfaces
  - ◆ smooth metal, smooth glass, smooth plastics
- specular reflection coefficient increases left to right

- specular exponent decreases left to right

## *Putting It All Together*

- the total reflected intensity is

$$\begin{aligned} I_{\text{total}} &= I_{\text{amb}} + I_{\text{diff}} + I_{\text{spec}} \\ &= I_a * \rho_a + I_s * \rho_d * \text{lambert} + I_s * \rho_s * \text{phong}^f \end{aligned}$$

- Hill writes  $I_{\text{total}}$  a little differently

$$I_{\text{total}} = I_a * \rho_a + I_d * \rho_d * \text{lambert} + I_{\text{sp}} * \rho_s * \text{phong}^f$$

- $I_d$  is the diffuse intensity of the light source
- $I_{\text{sp}}$  is the specular intensity of the light source

## *Putting It All Together (cont)*

- picture of spheres lit with Phong model

## *Adding Color*

- to add color

- ◆ source intensities are in (r, g, b)

- ◆ all reflection coefficients are in (r, g, b)

- ◆ curiously, f is a constant (not in (r, g, b))

- $I_{\text{total},r} = I_{a,r} * \rho_{a,r} + I_{d,r} * \rho_{d,r} * \text{lambert} + I_{sp,r} * \rho_{s,r} * \text{phong}^f$

- $I_{\text{total},g} = I_{a,g} * \rho_{a,g} + I_{d,g} * \rho_{d,g} * \text{lambert} + I_{sp,g} * \rho_{s,g} * \text{phong}^f$

- $I_{\text{total},b} = I_{a,b} * \rho_{a,b} + I_{d,b} * \rho_{d,b} * \text{lambert} + I_{sp,b} * \rho_{s,b} * \text{phong}^f$

- notice that it is possible for  $I_{\text{total}} > 1$

- ◆ usually  $I_{\text{total}}$  is clamped to the range [0, 1]

- if there are multiple lights, we compute  $I_{\text{total}}$  for each light and add up all of the contributions
